Part 1: A Few Things to Remember

I added the sourcing to my `.bashrc` file. Now upon opening a new terminal window, I get the following for these commands:

```
jackie@jackielaptop:~$ printenv | grep ROS
ROS_ROOT=/opt/ros/kinetic/share/ros
ROS_PACKAGE_PATH=/home/jackie/catkin_ws/src:/opt/ros/kinetic/share
ROS_MASTER_URI=http://localhost:11311
ROS_VERSION=1
ROSLISP_PACKAGE_DIRECTORIES=/home/jackie/catkin_ws/devel/share/common-lisp
ROS_DISTRO=kinetic
ROS_ETC_DIR=/opt/ros/kinetic/etc/ros
```

Part 2: The “Hello World!” Program

I created the package `hello` and edited `package.xml`. The entire package is in the zip folder in a folder called `hello`. `package.xml` is shown here for convenience.

I ran `roscore` in one terminal. Then I ran
`python hello.py`

I got

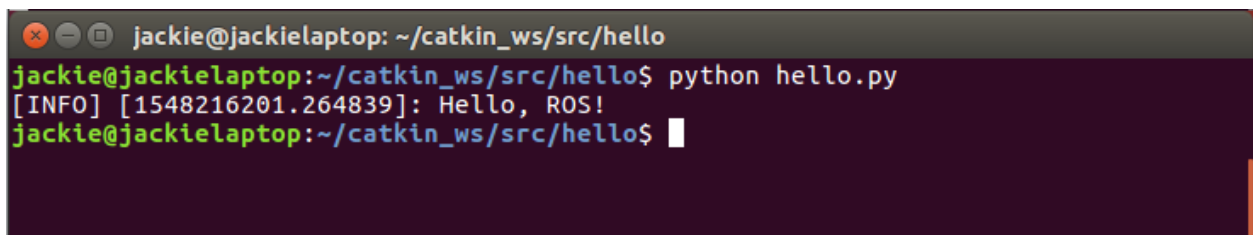

A terminal window with a dark background. The title bar shows 'jackie@jackielaptop: ~/catkin_ws/src/hello'. The prompt is 'jackie@jackielaptop:~/catkin_ws/src/hello\$'. The user has entered 'python hello.py'. The output is '[INFO] [1548216201.264839]: Hello, ROS!'. The prompt is now 'jackie@jackielaptop:~/catkin_ws/src/hello\$' with a cursor.

Figure 1: Output from `hello.py`

Basically, the node sends the one message and then quits. So by the time I run

```
roscore list
rostopic list
```

The node and from `hello.py` doesn't show up, because by the time I type those into the terminal window `hello.py` is done.

```
jackie@jackielaptop: ~  
jackie@jackielaptop:~$ rosnodetop  
/rosout  
jackie@jackielaptop:~$ rostopic list  
/rosout  
/rosout_agg  
jackie@jackielaptop:~$
```

Figure 2: Output from `rostopic list` and `rostopic list`

If it didn't quit right away, I believe I would be able to see a node called `/hello_ros`.

Part 3: A ROS Publisher Program

I ran `pubvel.py` while `turtlesim` was running.

1. Describe the behavior of the turtle under the control of the original `pubvel.py`.

The turtle moves around randomly. It quickly got stuck in a corner.

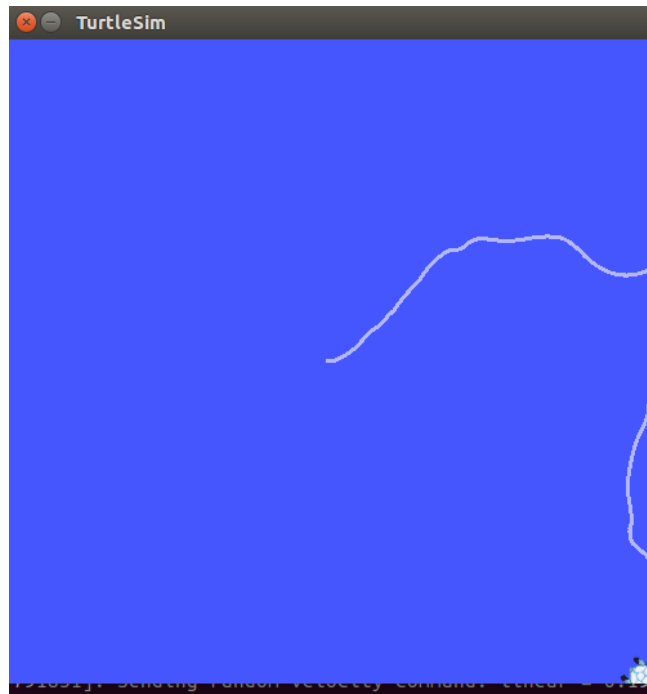

Figure 3: Output from original `pubvel.py`

2. Modify `pubvel` to make the turtle move on a circle. How could you make the circle larger?

I modified the code in `pubvel` to set the linear and angular velocity to 1. The code is in the zip folder.

Figure 4: Output from modified *pubvel.py*

To make the circle larger, the linear velocity can be increased or the angular velocity can be decreased. For example, setting `msg.linear.x = 2`, I got the following output:

Figure 5: When linear velocity is increased, the turtle traces a larger circle.

3. What is the code's intended rate of the publishing loop in *pubvel.py*?

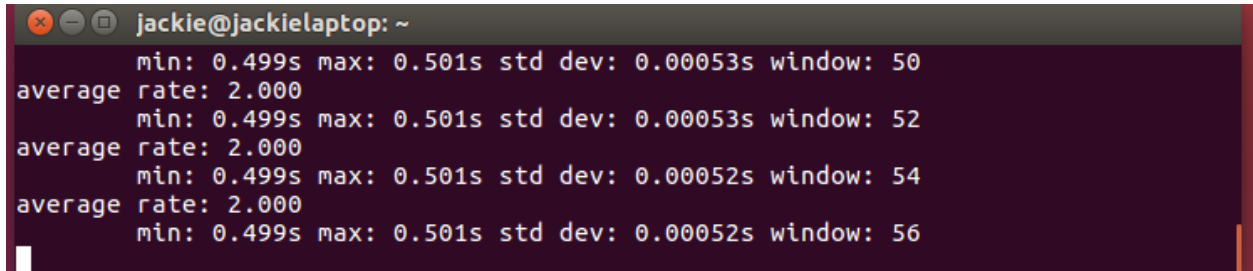

Line 17 shows us:

```
r = rospy.Rate(2)
```

This means that the node will attempt to publish the velocity command at a rate of 2 Hz, or every half second.

4. *What is the actual rate of publishing during execution? (The command `rostopic hz topicname` will be helpful)*

It's almost exactly 2Hz/.5 seconds:

A terminal window with a dark background and light-colored text. The title bar shows 'jackie@jackielaptop: ~'. The output of the 'rostopic hz' command is displayed for the 'turtle1/cmd_vel' topic. It shows four consecutive measurements, each with a minimum time of 0.499s, a maximum time of 0.501s, a standard deviation of 0.00053s or 0.00052s, and an average rate of 2.000. The window size for each measurement is 50, 52, 54, and 56 respectively.

```
jackie@jackielaptop: ~  
min: 0.499s max: 0.501s std dev: 0.00053s window: 50  
average rate: 2.000  
min: 0.499s max: 0.501s std dev: 0.00053s window: 52  
average rate: 2.000  
min: 0.499s max: 0.501s std dev: 0.00052s window: 54  
average rate: 2.000  
min: 0.499s max: 0.501s std dev: 0.00052s window: 56
```

Figure 6: Actual publishing rate on the `turtle1/cmd_vel` topic.

Part 4: A ROS Subscriber Program

I ran `subpose.py` while `turtlesim` was running.

5. *What is the purpose of `rospy.spin()` in this code?*

`rospy.spin()` stops the node from exiting, so it will keep performing all its functionality until otherwise shutdown. In this particular code, it means that it will keep listening for messages on `turtle1/pose` until otherwise shutdown.

6. *Use a ROS bag to collect the twist messages and plot them with `rqt plot`. Plot x-position vs time and x-velocity vs time. Based on your plots, comment on whether `turtlesim` correctly computes position from velocity.*

First, I plotted the twist messages:

Figure 7: The Twist messages. Essentially linear.x and angular.z are both at 1, and the rest are at 0. This matches what was programmed in `pubvel.py`.

Next I plotted x-velocity and x-position vs. time.

Figure 8: The x-position and x-velocity as calculated by Pose.

The velocity published by the Twist message (Figure 7) and then velocity calculated by turtlesim and published as part of Pose (Figure 8) are the same, 1 unit/s. Thus turtlesim calculates these correctly.

We can also view the velocity in the world frame rather than in the turtle frame. The area under the curve is equal to the position as calculated by turtlesim:

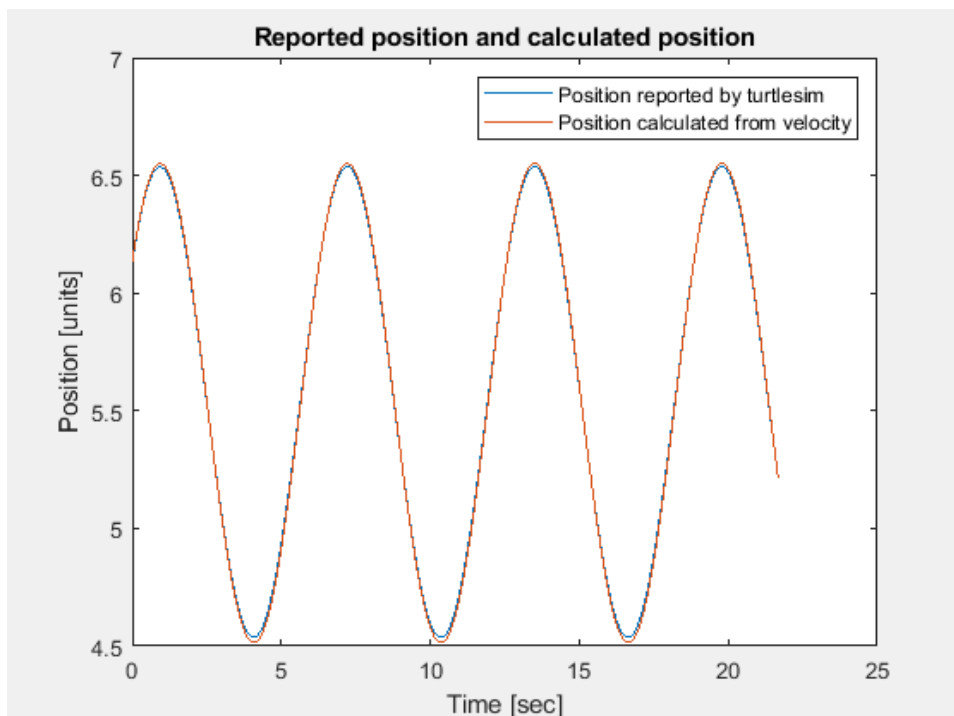

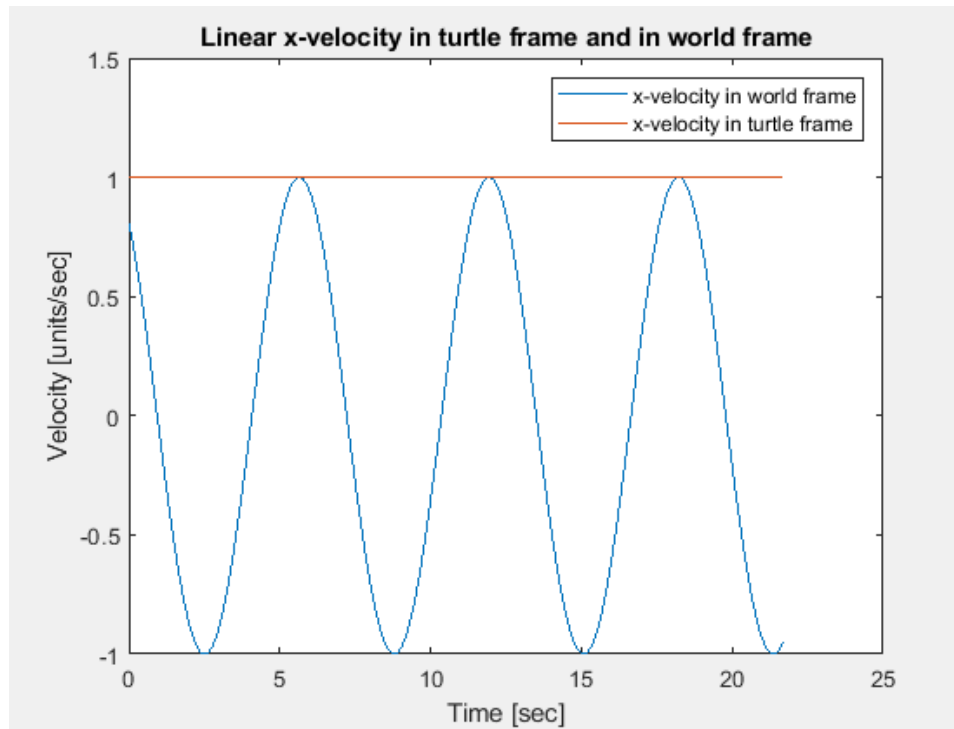

Figure 9: World frame velocity is used to show that the area under this curve is equal to the position.

The code to create these graphs is in PA1.m in the assignment folder.

7. After running the simulator, use `rqt plot` to plot y-position vs x-position. Compare this with a screenshot from the turtle simulator to show that your plot is correct. I used `rqt_multiplot`.

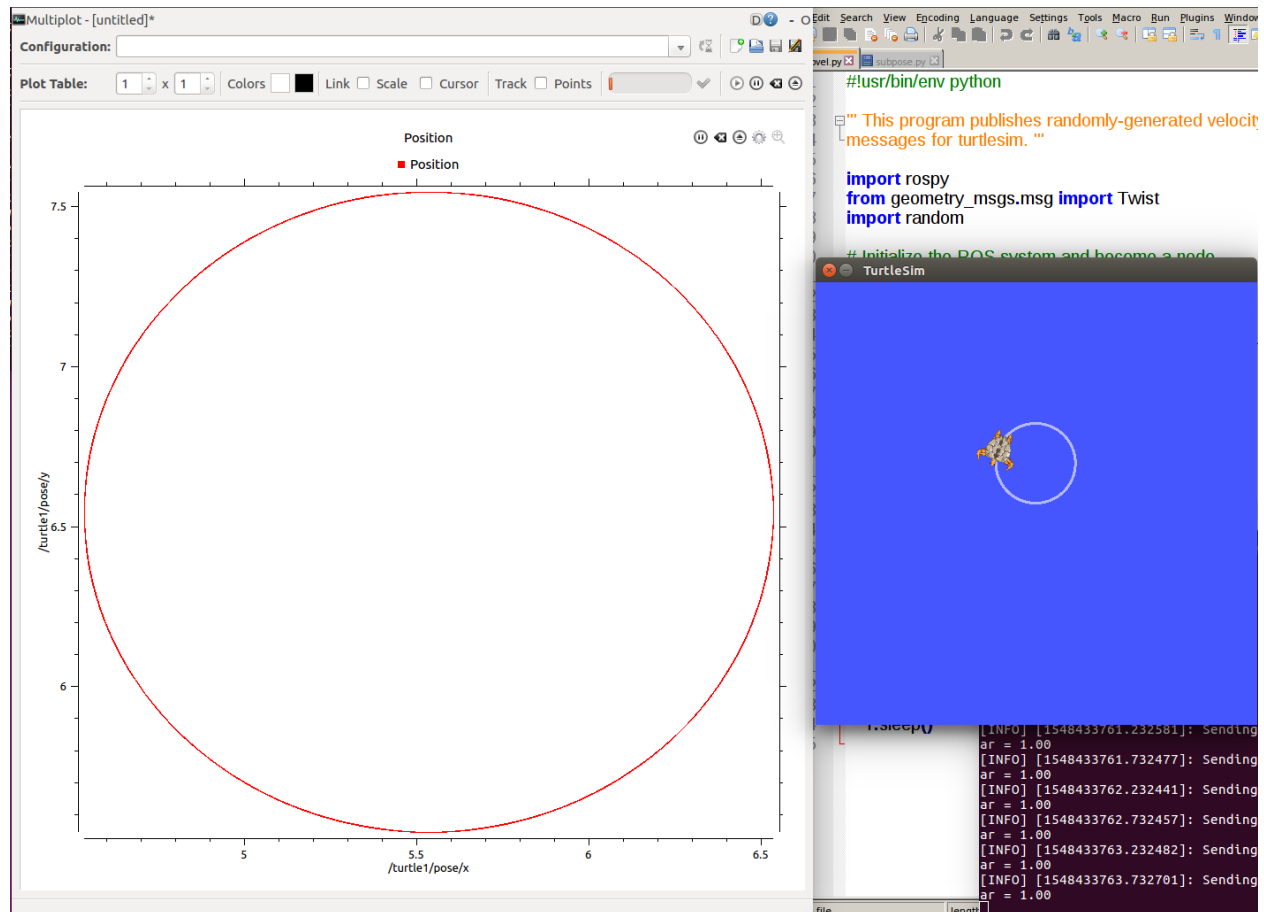

Figure 10: Plot of x vs. y using `rqt_multiplot`, compared to `turtlesim`.

Useful things I learned:

- I learned that the Pose message publishes linear and angular velocity, not just position and orientation
- Learned how to use `rqt_multiplot` to plot anything on the x-axis, not just time as `rqt_plot` permits
- Used the command `roscd` a lot to navigate quickly to my hello package
- Learned how to import bag files into Matlab
- Learned how to take screenshots on Ubuntu using the built in screenshot tool
